

1 **EXECUTIVE SUMMARY**

2 **INTRODUCTION**

3 The San Francisco Bay Estuary (Estuary) supports the largest and most ecologically important ex-  
4 panses of tidal mudflats and salt marshes in the contiguous western United States. This environ-  
5 ment supports a diverse array of native plants and animals. Over the years, many non-native spe-  
6 cies of plants and animals have been introduced to the Estuary, and some now threaten to cause  
7 fundamental changes in the structure, function, and value of the Estuary’s tidal lands. Among these  
8 threatening invaders are several species of salt marsh cordgrass (genus *Spartina*). In recent decades,  
9 populations of non-native cordgrasses were introduced to the Estuary and began to spread rapidly.  
10 Though valuable in their native settings, these introduced cordgrasses are highly aggressive in this  
11 new environment, and frequently become the dominant plant species in areas they invade.

12 One of the non-native cordgrass species in particular, Atlantic smooth cordgrass, and its hybrids  
13 (formed when this species crosses with the native Pacific cordgrass) are now threatening the eco-  
14 logical balance of the Estuary and are likely to eventually cause the extinction of native Pacific  
15 cordgrass, choke tidal creeks, dominate newly restored tidal marshes, and displace thousands of  
16 acres of existing shorebird habitat. Once established in this Estuary, invasive cordgrasses could  
17 rapidly spread to other estuaries along the California coast through seed dispersal on the tides.  
18 Non-native invasive cordgrasses dominate greater than 500 acres of San Francisco Estuary mud-  
19 flats and tidal marsh – on State, Federal, municipal, and private lands – and are spreading rapidly.  
20 The *Spartina* Control Program (Control Program) proposes to implement a coordinated, region-  
21 wide eradication program, comprising a number of on-the-ground treatment techniques to stave  
22 off this invasion. The Control Program will be focused within the nearly 40,000 acres of tidal  
23 marsh and 29,000 acres of tidal flats that comprise the shoreline areas of Alameda, Contra Costa,  
24 Marin, Napa, San Francisco, San Mateo, Santa Clara, Solano, Sonoma, and Sacramento counties.

25 The California State Coastal Conservancy (Conservancy), as the lead agency under the California  
26 Environmental Quality Act (CEQA), and the U.S. Fish and Wildlife Service (Service or USFWS),  
27 as the lead agency under the National Environmental Policy Act (NEPA), have jointly prepared  
28 this Environmental Impact Statement/Report EIS/R to address the environmental impacts of the  
29 proposed Control Program. This document is a “Programmatic” EIS/R (NEPA Regulations Sec-  
30 tion 1508.18 and CEQA Guidelines Section 15168) because it analyzes the potential effects of im-  
31 plementing treatment methods for a regional program, rather than the impacts of an individual  
32 treatment project.

33 **PURPOSE AND NEED**

34 The purpose of the *Spartina* Control Program is to arrest and reverse the spread of invasive non-  
35 native cordgrass species in the Estuary to preserve and restore the ecological integrity of the Estu-  
36 ary’s intertidal habitats and estuarine ecosystem.

37 The Control Program is needed to prevent further degradation and loss of the natural ecological  
38 structure and function of the Estuary. Within decades, half of the existing intertidal flats are likely  
39 to be replaced with dense, invasive non-native cordgrass marsh, and much of the native diverse

1 salt-marsh vegetation replaced with nearly single-species stands of invasive non-native cordgrass  
2 marsh.

3

4 Potential effects of non-native cordgrass invasion include:

- 5 • Genetic assimilation and extinction of native Pacific cordgrass;
- 6 • Extensive regional loss of tidal flats;
- 7 • Elimination of critical foraging habitat for migratory shorebirds;
- 8 • Failure of efforts to restore native tidal marsh vegetation in diked baylands;
- 9 • Interference with natural sedimentation processes to support restoration of diked baylands;
- 10 • Regional loss of tidal sloughs and channels;
- 11 • Stabilization of estuarine beaches and beach-forming processes;
- 12 • Marginalization of endangered California clapper rail habitat;
- 13 • Reduction or elimination of endangered salt marsh harvest mouse habitat;
- 14 • Interference with recovery of endangered California sea-blite;
- 15 • Increased need for dredging and flood control;
- 16 • Production of massive piles of vegetative debris; and,
- 17 • Spread of non-native cordgrasses to other California estuaries.

18 Arresting and reversing the invasion of non-native cordgrasses may become infeasible once these  
19 species have spread and become established, due to the aerial extent of the invasion and the effects  
20 of hybridization. Therefore, the Control Program will take immediate and aggressive action to op-  
21 timize the potential for success.

## 22 **PROGRAM ALTERNATIVES**

23 The lead agencies evaluated a number of approaches and a variety of treatment methods that may  
24 achieve the project goal. Three alternatives were ultimately selected for full evaluation. The two  
25 “action alternatives,” Alternatives 1 (Regional Eradication Using All Available Control Methods)  
26 and 2 (Regional Eradication Using Only Non-Chemical Control Methods), would employ a variety  
27 of manual and mechanical treatment methods, including:

- 28 • Hand-pulling and manual excavation;
- 29 • Mechanical excavation and dredging;
- 30 • Pruning, burning, and mowing;
- 31 • Smothering (blanketing); and
- 32 • Drowning.

33 In addition to these methods, Alternative 1, the preferred alternative, would also employ applica-  
34 tion of herbicides in suitable situations.

35 Both Alternatives 1 and 2 would incorporate a modified Integrated Vegetation Management (IVM)  
36 approach. The IVM approach will integrate scientific information regarding cordgrass and the es-  
37 tuarine ecosystem with awareness of the likely economic, ecological, and sociological consequences

1 of the cordgrass invasion, to assure a program that is effective, economical, and protective of pub-  
2 lic and environmental health.

3 Consistent with NEPA and CEQA requirements, a no-action alternative, Alternatives 3, also was  
4 developed and evaluated. Under Alternative 3, no regional program to control non-native invasive  
5 cordgrasses would be adopted, however the current approach of limited uncoordinated control  
6 efforts would continue. **Table S-1** provides an abbreviated description of the three alternatives for  
7 reference.

## 8 ENVIRONMENTAL IMPACTS, AND MITIGATION MEASURES

9 The environmental impacts of the project and alternatives are summarized on **Table S-2** and are  
10 briefly described by topic below.

### 11 Geomorphology and Hydrology

12 Manual and mechanical treatment under Alternatives 1, 2, and 3 could have adverse effects of in-  
13 creased erosion (in some limited circumstances) and competition for limited sediment disposal  
14 sites during treatment. These impacts would either be less than significant or could be mitigated to  
15 less than significant levels by implementation of mitigation measures identified in this EIS/R.  
16 These alternatives would have a beneficial effect on flows of water in tidal channels.

### 17 Water Quality

18 Implementation of Alternatives 1 and 3 could adversely affect water quality due to herbicide appli-  
19 cation, spills of herbicides and petroleum products, and remobilization of contaminants in sedi-  
20 ments. Alternative 2 would not have herbicide-related impacts, but would share approximately the  
21 same level of other water quality-related potential impacts as Alternatives 1 and 3. Under all of the  
22 alternatives, impacts to water quality would either be less than significant or could be mitigated to  
23 less than significant levels by implementation of mitigation measures identified in this EIS/R.

### 24 Biological Resources

25 In general, Alternatives 1 and 2 would have significant adverse short-term impacts, while Alterna-  
26 tive 3 would have significant unavoidable long-term impacts associated with the conversion of  
27 habitat resulting from the spread of non-native cordgrasses, as summarized below:

- 28 • Alternatives 1, 2, and 3 could have significant but mitigable effects on non-target plant spe-  
29 cies in infested areas, primarily as a result of disturbance required to eradicate the invasive  
30 plants.
- 31 • These alternatives also could have short-term adverse significant and mitigable impacts to  
32 submerged aquatic plant communities, shorebird and waterfowl habitat, harbor seal haul

Table S-1. Alternatives Analyzed in This EIS/R

<i>Alternative</i>	<i>Description</i>
<b>1</b>	Proposed Action/ Proposed Project - Regional Eradication Using All Avail- able Control Methods
<b>2</b>	Regional Eradication Using Only Non-Chemical Control Methods
<b>3</b>	No Action – Continued Limited, Regionally Uncoordinated Treatment

1           outs, and special status plants. In the long term, Alternatives 1 and 2 would not adversely  
2           affect these biotic resources, while Alternative 3 would significantly and unavoidably ad-  
3           versely affect them.

- 4           • Alternatives 1, 2, and 3 would have significant short-term impacts to the salt marsh harvest  
5           mouse and tidal shrew species due to habitat disturbance resulting from treatment activi-  
6           ties. However, long-term spread of non-native cordgrasses significantly adversely affect  
7           these species under Alternative 3.
- 8           • California clapper rail and black rail populations would be significantly adversely and un-  
9           avoidably affected in the short-term by treatment activities under Alternatives 1 and 2, and  
10          in the long-term under Alternative 3.
- 11          • Estuarine fishes and anadromous salmonids would be subject to significant but mitigable  
12          adverse short-term impacts from treatment activities under Alternatives 1, 2, and 3, and to  
13          significant unavoidable long-term impacts under Alternatives 3.
- 14          • San Francisco garter snake, California red-legged frogs, and tidewater gobies would not be  
15          significantly affected under any alternatives.
- 16          • All alternatives would have either less than significant or significant but mitigable effects on  
17          increased mosquito production.

## 18   **Air Quality**

19   Alternatives 1, 2, and 3 would have less than significant effects on emissions of air contaminants  
20   and dust with the exception of herbicides, which could be significant but mitigable under Alterna-  
21   tives 1 and 3.

## 22   **Noise**

23   Sensitive noise receptors could experience significant but mitigable impacts as a result of noise  
24   generated by treatment activities under Alternatives 1, 2, and 3.

## 25   **Human Health and Safety**

26   Workers involved in herbicide treatment could be subject to significant but mitigable health risks  
27   under Alternatives 1 and 3. All other human health and safety impacts would be either less than  
28   significant or non-existent under all alternatives.

## 29   **Visual Resources**

30   Removal of large areas of invasive cordgrass could have significant, unmitigable temporary adverse  
31   visual impacts under Alternatives 1, 2, and 3. Conversely, Alternatives 3 would result in long-term,  
32   significant, unavoidable visual impacts resulting from elimination of mudflats and the native-like  
33   variation in visual character that currently characterizes the Bay margins.

## 34   **Land Use**

35   Herbicide use under Alternatives 1 and 3 could result in significant adverse temporary land use  
36   conflicts with residents and recreational users in the vicinity of the areas to be sprayed. This is  
37   mitigable by implementation of notification and herbicide control measures identified in this  
38   EIS/R. Alternative 2 would avoid this impact.

1 **Cultural Resources**

2 Treatment activities under Alternatives 1, 2, and 3 could adversely affect historic or prehistoric  
3 cultural resources. However these potentially significant impacts could be reduced to less than sig-  
4 nificant by implementation of monitoring and avoidance measures identified in this EIS/R.

5 **Socioeconomics**

6 None of the alternatives would have a significant effect, either beneficial or adverse, on socioeco-  
7 nomic conditions.

8 **Environmental Justice**

9 None of the alternatives would have a significant effect on environmental justice issues.

10 **Cumulative Impacts**

11 Three types of projects have potential significant cumulative interactions with the Control Pro-  
12 gram: (1) other aquatic weed control programs in the Bay-Delta (Sacramento-San Francisco River  
13 Delta) region; (2) mosquito abatement activities in tidal marshes of the Bay region; and (3) restora-  
14 tion and management projects affecting tidal marshes of the San Francisco Estuary. A risk of sig-  
15 nificant damage to marsh plain vegetation from cumulative vehicle use from mosquito abatement  
16 activities and the Control Program could occur. Mitigations that reduce this impact to less than  
17 significant levels are identified in this document.

18 In addition, proposed wetland restoration projects could accelerate the spread of non-native cord-  
19 grass, which in turn, could interfere with the effectiveness of the Control Program. This would re-  
20 sult in significant and adverse effects on biological resources, Estuary hydrology, and geomorphol-  
21 ogy. This is mitigable via proper sequencing of restoration projects and the Control Program.

22 **Unavoidable Significant Impacts**

23 The Control Program would result in significant unavoidable impacts to the salt-marsh harvest  
24 mouse, tidal shrew, California clapper rail, California black rail, and short-term visual quality of  
25 treated marshes.

26 **COMPARISON OF ALTERNATIVES**

27 There is a strong contrast in the comparisons of alternatives from the perspectives of long-term  
28 versus short-term environmental consequences. Normally, with private development or public  
29 works projects, the “no action” alternative is associated with more environmentally benign protec-  
30 tion or conservation of existing natural resources. In this case, the existing natural resources are  
31 undergoing long-term degradation because of “biological pollution” caused by non-native invasive  
32 cordgrass species.

33 Alternatives 1 and 2 cause significantly more adverse short-term, direct, and indirect environmental  
34 impacts than the no action Alternative 3, which would still have potentially significant treatment  
35 impacts. These short-term impacts are the inevitable consequences of eradication methods that  
36 devegetate tidal wetlands invaded by non-native cordgrass. Alternatives 1 and 2, and to a lesser  
37 extent Alternative 3 eliminate or displace the wildlife that inhabit them, and cause significant short-  
38 term side effects from operation of vehicles and equipment. Alternative 2 would have no short-

1 term, direct, and indirect impacts related to application of aquatic herbicides, such as operation of  
2 helicopters and vehicles, and risk of spray drift, overspray and accidental spillage. However, re-  
3 peated physical eradication methods that may be necessary to replace chemical herbicides, the po-  
4 tential ground and vegetation disturbance impacts under Alternative 2 would increase. This would  
5 shift some impacts from aquatic environments (potential herbicide dispersion impacts) to marsh  
6 environments (increased intensity, frequency, and duration of mechanical disturbance). Thus, Al-  
7 ternative 2 could prolong wetland degradation and ultimately exceed the net impact of combined  
8 use of manual, mechanical, and chemical methods proposed in Alternative 1. Alternative 3's lack of  
9 coordination would exacerbate this impact, compared with Alternative 2.

10 Alternative 2 also has a higher risk of failure to control and eventually eradicate invasive cord-  
11 grasses compared to Alternative 1. If Alternative 2 failed to control these invasives, it eventually  
12 would result in the same long-term environmental consequence as described below for Alternative  
13 3. Alternative 3's lack of regional coordination would allow the continued and quickening spread  
14 of Atlantic smooth cordgrass. This would result in diminishing local control effectiveness and in-  
15 creasing local costs for non-native cordgrass "maintenance" control over time. Probably within  
16 one to two decades, only flood control and navigation interests would have incentives and re-  
17 sources to combat overwhelming invasion rates of Atlantic smooth cordgrass hybrids, especially if  
18 tidally restored salt ponds generate vast new hybrid populations and seed sources.

### 19 **Environmentally Superior (CEQA) and Preferred (NEPA) Alternative**

20 Because the project is, in effect, an environmental restoration and protection project, its primary  
21 adverse impacts are short-term, during the treatment process. As described above, Alternatives 2  
22 could have somewhat less environmental impacts than Alternative 1 because it would exclude im-  
23 pacts related to application of aquatic herbicides.. However, these reduced impacts could be offset  
24 by the need for additional mechanical treatment if chemicals are not used, and by the potential im-  
25 pacts resulting from repeated treatment under Alternative 2. In addition, Alternative 2 also has a  
26 lower probability of achieving the project's ultimate environmental benefits than Alternative 1.  
27 Similarly, Alternative 3 would somewhat reduce treatment impacts, but is likely to ultimately fail,  
28 resulting in far greater long-term impacts than Alternative 1 and, likely, Alternative 2. Therefore  
29 this EIR considers the CEQA Environmentally Superior Alternative to be a mitigated version of  
30 Alternative 1 in which all mitigations in this EIS/R have been incorporated into the program. This  
31 Environmentally Superior Alternative is identified as the Mitigated Project Alternative.

32 Similarly, the Federal lead agencies have concluded that Alternative 1 is most likely to achieve long-  
33 term protective benefits for California's estuarine environments, and provide the most favorable  
34 ratio of environmental costs to benefits. Therefore, Alternative 1 with inclusion of EIS-identified  
35 mitigation measures is identified as the NEPA Environmentally Preferred Alternative.
